Point-free language

- No variables are used
- Categorically-inspired combinators
- Algebraic data types as fixed points of functors
- Polytypic recursion patterns

Introduction

Cata-FUSION for Lists

Conclusions

Main Goal

Why *Point-free*

Easy to prove
reason equationally

DRHYLO

- Translation from *pointwise* to *point-free*
- Removal of explicit recursion
- Automated process
⇒ *Complex point-free results*

Reason automatically on *point-free* terms

Main Goal

Why *Point-free*

Easy to prove
reason equationally

DRHYLO

Examples

Rule construction

Basic Principles

Main Problems

Testing Strategies

Simple Strategy

Cata-Fusion for Lists

Conclusions

- Simplification and Transformation of *point-free* terms
- *Active source* – Code with special commented blocks
- Rules and strategies to transform terms
- Strategies implemented with generic traversals - *Strafunski*
- Uses *Haskell* patterns matching
- Visualisation of intermediate steps

rulePF :: (MonadPlus m) =>
  String -> (Term -> m Term)
         -> TU Computation m
```

```
rulePF name rule =
  ... collect original term
  (once_tdTP (adhocTP failTP rule)
  `seqTP` normalizestrat
  ... get new term, and create new Computation
```

More Complete Justifications

In final version:

- Rules can apply strategies in the right-hand side;
- Justifications are now a string and a list of Computations;
- Redefinition of `Computation`

$$\begin{aligned} \textit{Computation} &= \textit{Result Steps} \\ \textit{Step} &= (\textit{Term}, \textit{Computations}, \textit{String}) \end{aligned}$$

- Strategy combinators a bit more complex.

Testing Strategies

Simple Strategy

Cata-FUSION for Lists

Conclusions

- A rule is a function with type `Term -> m Term`;
- Tries to apply a transformation to a term or a prefix of a term;
- Assumes composition is *normalized*.

Example: `natId1 : id ∘ f → f`

```
natId1 (ID :: f) = return f
natId1 _         = fail "..."
```

- A rule is a function with type `Term -> m Term`;
- Tries to apply a transformation to a term or a prefix of a term;
- Assumes composition is *normalized*.

Example: $\text{natId}_1 : \text{id} \circ f \rightarrow f$

```
natId1 (ID ::: f) = return f
natId1 _          = fail "..."
```

First Complication

Matching a prefix of a composition.

When the matching term is a composition,
not ending on a variable.

Addition of a new match to the function.

Example: $sumCancel_1 : (f \nabla g) \circ inl \rightarrow f$

```
sumCancel1 ((f :: g) :: INL)
  = return f
sumCancel1 ((f :: g) :: (INL :: x))
  = return (f :: x)
sumCancel1 _
  = fail "..."
```

  = return f
sumCancel1 ((f :: g) :: (INL ::: x))
  = return (f ::: x)
sumCancel1 _
  = fail "..."
```

Left variables

The Problem

Oops: Variables on the left of compositions.

Why?

- Composition is associated to the right;
- Different associations until a pattern matching is found.

Example

$$\overline{f \circ ap}$$

would not match any subterm of

$$\overline{fst \circ (snd \circ ap)}$$

Left variables

The Problem

Oops: Variables on the left of compositions.

Why?

- Composition is associated to the right;
- Different associations until a pattern matching is found.

Example

$$\overline{f \circ ap}$$

would not match any subterm of

$$\overline{fst \circ (snd \circ ap)}$$

Conclusions

Left Variables

Solution

Replace compositions with *left variables* for new variables.

Use **auxiliary functions** for these subterms.
Still using *Haskell* pattern matching.

The auxiliary functions use an intermediate structure –
Maybe ([Term], Maybe Term) – to:

- check if the pattern matching succeeded;
- return the values of variables inside subterm;
- return the possible *ending*.

Left Variables

Solution

Replace compositions with *left variables* for new variables.

Use **auxiliary functions** for these subterms.
Still using *Haskell* pattern matching.

The auxiliary functions use an intermediate structure –
Maybe ([Term], Maybe Term) – to:

- check if the pattern matching succeeded;
- return the values of variables inside subterm;
- return the possible *ending*.

Left Variables

Solution

Replace compositions with *left variables* for new variables.

Use **auxiliary functions** for these subterms.
Still using *Haskell* pattern matching.

The auxiliary functions use an intermediate structure – **Maybe** `([Term], Maybe Term)` – to:

- **check if the pattern matching succeeded;**
- return the values of variables inside subterm;
- return the possible *ending*.

Left Variables

Solution

Replace compositions with *left variables* for new variables.

Rule construction

Basic Principles

Main Problems

Testing Strategies

Simple Strategy

Cata-FUSION for Lists

Conclusions

Conditions

Solution – Not Regarding *Left Variables*

Introduction of a new match when composition ends in a variable:

```
rule (... :: f :: x) | cond  
  = return ( exp :: x)
```

```
rule (... :: f :: (x1 :: x2))  
  = rule (... :: ( f :: x1 ) :: x2)
```

```
rule (... :: f ) | cond  
  = return exp
```

Conditions

Solution – In the presence of *Left Variables*

Auxiliary functions collect all possible matches for each variable.

Intermediate structure of auxiliary functions change:

from `Maybe ([Term], Maybe Term)`
to `[([Term], Maybe Term)]`

When a match is found in a *composition** ending in a *variable*:

Keep searching for more matches.

Use the first match that validates the conditions.

Conditions

Solution – In the presence of *Left Variables*

Auxiliary functions collect all possible matches for each variable.

Intermediate structure of auxiliary functions change:

from `Maybe ([Term], Maybe Term)`
to `[([Term], Maybe Term)]`

When a match is found in a *composition** ending in a *variable*:

Keep searching for more matches.

Use the first match that validates the conditions.

from `Maybe ([Term], Maybe Term)`
to `[([Term], Maybe Term)]`

When a match is found in a **composition*** ending in a **variable**:

Keep searching for more matches.

Use the first match that validates the conditions.

Syntactic Sugar

Making Life Easier

- Equal variables

- Associativity property:

Given \oplus produces $\bar{\oplus} \circ \oplus \rightarrow \text{comp} \circ (\bar{\oplus} \times \bar{\oplus})$

- Fold and unfold macros, based on its definition.

- Introduction of lists of terms.

Conclusions and Future Work

What was done:

- Automated simplification of *point-free* terms;
- Easy definition of strategies and rules;
- Program transformation – cata-FUSION

Future Work:

- Formal validation;
- Use of type information;
- Generalise cata-FUSION;
- Loop detection;
- Improve rules repository.
